

CS188: Exam Practice Session 6

Q1. Variable Elimination

For the Bayes' net shown on the right, we are given the query $P(B, D \mid +f)$. All variables have binary domains. Assume we run variable elimination to compute the answer to this query, with the following variable elimination ordering: A, C, E, G .

- (a) Complete the following description of the factors generated in this process:

After inserting evidence, we have the following factors to start out with:

$$P(A), P(B|A), P(C|B), P(D|C), P(E|C, D), P(+f|C, E), P(G|C, +f)$$

When eliminating A we generate a new factor f_1 as follows:

$$f_1(B) = \sum_a P(a)P(B|a)$$

This leaves us with the factors:

$$P(C|B), P(D|C), P(E|C, D), P(+f|C, E), P(G|C, +f), f_1(B)$$

- (i) When eliminating C we generate a new factor f_2 as follows:

This leaves us with the factors:

- (ii) When eliminating E we generate a new factor f_3 as follows:

This leaves us with the factors:

- (iii) When eliminating G we generate a new factor f_4 as follows:

This leaves us with the factors:

- (b) Explain in one sentence how $P(B, D \mid +f)$ can be computed from the factors left in part (iii) of (a)?

- (c) Among f_1, f_2, \dots, f_4 , which is the largest factor generated, and how large is it? Assume all variables have binary domains and measure the size of each factor by the number of rows in the table that would represent the factor.

For your convenience, the Bayes' net from the previous page is shown again below.

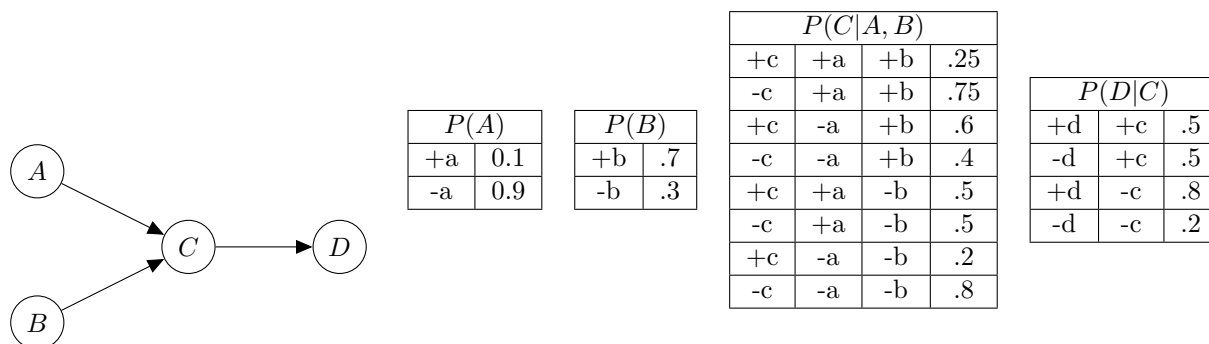

- (d) Find a variable elimination ordering for the same query, i.e., for $P(B, D \mid +f)$, for which the maximum size factor generated along the way is smallest. Hint: the maximum size factor generated in your solution should have only 2 variables, for a table size of $2^2 = 4$. Fill in the variable elimination ordering and the factors generated into the table below.

Variable Eliminated	Factor Generated

For example, in the naive ordering we used earlier, the first line in this table would have had the following two entries: A , $f_1(B)$. For this question there is no need to include how each factor is computed, i.e., no need to include expressions of the type $= \sum_a P(a)P(B|a)$.

Q2. Bayes' Net Sampling

Assume you are given the following Bayes' net and the corresponding distributions over the variables in the Bayes' net.

- (a) Assume we receive evidence that $A = +a$. If we were to draw samples using rejection sampling, on expectation what percentage of the samples will be **rejected**?

- (b) Next, assume we observed both $A = +a$ and $D = +d$. What are the weights for the following samples under likelihood weighting sampling?

Sample	Weight
$(+a, -b, +c, +d)$	
$(+a, -b, -c, +d)$	
$(+a, +b, -c, +d)$	

- (c) Given the samples in the previous question, estimate $P(-b | +a, +d)$.

- (d) Assume we need to (approximately) answer two different inference queries for this graph: $P(C | +a)$ and $P(C | +d)$. You are required to answer one query using likelihood weighting and one query using Gibbs sampling. In each case you can only collect a relatively small amount of samples, so for maximal accuracy you need to make sure you cleverly assign algorithm to query based on how well the algorithm fits the query. Which query would you answer with each algorithm?

Algorithm	Query	Algorithm	Query
Likelihood Weighting		Gibbs Sampling	

Justify your answer:
